ABSTRACT

The efficacy of lessenta 80 WG (fipronil 40%+ imidacloprid 40%WG) @ 125, 100 and 75 g ai/ ha was evaluated against sucking pests of cotton in comparison with the fipronil 5%SC @ 125 g ai/ ha, imidacloprid 17.8 SL @ 250 g ai/ ha, lambda-cyhalothrin 5%EC @ 600 g ai/ ha and monocrotophos 36%SL @ 437 g ai/ ha at the Agricultural Research Station, Dharwad, Karnataka, India. Fipronil 40%+ imidacloprid 40%WG @ 125 g ai/ ha recorded significantly minimum (8.25 and 3.01) *Thrips tabaci* (Lindeman) (Thysanoptera: Thripidae) and *Amrasca biguttula biguttula* (Ishida) (Hemiptera: Cicadellidae) incidence, respectively followed by lessenta 80 WG @ 100 g ai/ ha (8.68 and 3.42, respectivey) and fipronil 40%+ imidacloprid 40%WG @ 75 g ai/ ha (9.55 and 3.98, respectively). Further, significantly highest seed cotton yield of 13.99 q/ha, 13.58 q/ha and 12.86 q/ha, respectively were harvested from the fipronil 40%+ imidacloprid 40%WG treatments proving them better choice in effective management of both *A. biguttula biguttula* and *T. tabaci* incidence.

Key words: Lessenta, fipronil, imidacloprid, sucking pests, *Thrips tabaci, Amrasca biguttula biguttula*, natural enemies, cotton, combi-product, leafhopper, coccinellids, chrysopids.

Cotton (Gossypium spp.) has more than 200 genera and about 2300 species. It belongs to family Malvaceae. There are more than 50 species under genus Gossypium reported till now, which are native to Africa, Australia, Central and South America and Asia (Fryxell 1992; Wendel and Grover 2015). Only four species are widespread and used for commercial cultivation- two diploid (2n = 26) species, namely Gossypium arboreum and Gossypium herbaceum belong to old world cotton and two tetraploid (2n = 52) species, namely Gossypium barbadense and Gossypium hirsutum belong to new world cotton (Lu et al., 1997). India occupy largest cotton acreage (13.373 mha) and production (36.5 m bales, 1 bale=170 kg) in the world (CICR, 2020). Though, India shares largest area under cotton, however Indian cotton productivity is lowest (464 kg lint/ ha) due to variety of reasons, among them damage due to various arthropod pests is one of the major yield limiting factors (Nagrare et al., 2022). The low yields (up to 35–40%) are mainly attributable to insect pests. Presently the cotton crop in India is attacked by 251 arthropod pest species (including insect and mites) belonging to 9 different insect orders and one order from Acarina. Among these species, about 12 species of insects are major pests during last two decades causing overall losses to the tune of 20-60% to cotton crop while remaining species are occasional, sporadic or minor in nature (Nagrare et al., 2022). Sap feeders viz., leafhopper, Amrasca biguttula biguttula and thrips, Thrips tabaci Linnaeus damage the cotton crop with regular occurrence at different growth stages, reducing the growth and yield (Bheemanna et al., 2015, Nagrare et al., 2022). The damage inflicted by insect pests has been considered important; leafhoppers are undoubtedly more severe among the many destructive sucking pests of cotton. The estimated loss due to sucking pests is up to 21.20% (Dhawan et al., 1988). The nymphs and adults suck the plant sap mainly from the lower surface of leaves and cause phytotoxic symptoms known as hopper burn which results in complete desiccation and has become one of the limiting factors in economic productivity of the crop. The introduction of synthetic pyrethroids, though brought desirable control of bollworms, resulted in resurgence of sucking pests have also been reported in cotton system due to excessive use of synthetic pyrethroids (Ajri et al., 1986; Patel et al., 1986). Imidacloprids, a neonicotinoid known for its efficacy against sucking pests (Giraddi et al., 2017) and fipronil belongs to a new class of insecticides fiproles and was found to be efficient compared to pyrethroid, OP and carbomate insecticides (Patil and Rajanikanth, 2004). Fipronil and imidacloprid are the two ingredients

in the combi product, Lessenta 80 WG having different mode of action is evaluated for its bio-efficacy against sucking pests of cotton i.e., leafhoppers, *A. biguttula biguttula* and *T. tabaci*.

MATERIALS AND METHODS

Field study was under taken at the Agricultural Research Station, Dharwad farm, Dharwad (15.4889° N, 74.9813° E) during kharif, 2017-18 and 2019-20 to evaluate bio-efficacy of Lessenta 80 WG (fipronil 40%+ imidacloprid 40%WG) against sucking pests of cotton. The experiment was laid out in randomized block design (RBD) with 8 treatments (T_1 - Control; T_2 -(Fipronil 40%+ Imidacloprid 40%WG) @ 75 g ai/ha; T, - (fipronil 40%+ imidacloprid 40%WG) @ 100 g ai/ ha; T₄ - (fipronil 40%+ imidacloprid 40%WG) @ 125 g ai/ ha; T₅ - fipronil 5 %SC @ 125 g ai/ ha; T₆ - Imidacloprid 17.8%SL @ 250 g ai/ ha; T₇ - lamda-cyhalothrin 5%EC (a) 600 g ai/ ha and T_o - monocrotophos 36% SL (a) 437 g ai/ha) replicated thrice. Cotton Hybrid "SP 911" which is susceptible for sucking pest attack was selected for the study. The cotton seeds were dibbled manually in experimental field, with a plot of 5 x 5 sq. m for each treatment and 30 x 10 cm spacing was maintained. All agronomic practices with recommended dose of fertilizers were followed to maintain good plant stand till the harvest of crop and harvesting was done manually. The treatments were imposed as and when sucking pests crossed ETL viz., 2 nymphs of Amrasca biguttula biguttula, or 10 nymphs/adults of T. tabaci per leaf. At an interval of 15 days, two sprays of insecticides were sprayed.

The incidence of sucking pests viz., T. tabaci and A. biguttula biguttula were recorded from randomly selected five plants per plot. Observations were recorded one day before spray (DBS) and at 1st, 3rd, 5th, 7th and 10th days after spray (DAS). Later, the mean of all the data of the pest incidence after spray was calculated. Observations of the mean of first sprays of both the seasons were averaged to get the pooled mean of both the seasons. Similarly, it was followed for the second spray and the mean of first and second sprays of both the seasons. Further, seed cotton was harvested from each treatment and finally expressed yield in q/ha. Observations were subjected to RBD ANOVA single factor statistical analysis using OPSTAT software to assess the impact of a combi product on pest incidence. Reduction of pest incidence in the treatments over untreated check was also calculated.

RESULTS AND DISCUSSION

A day before the execution of treatment for both the sprays, incidence of sucking pest was relatively uniform and above the Economic Threshold Level (ETL) in both the seasons during the vegetative stage of the crop (Table 1). Though the data is recorded a day before spray (DBS) and at 1st, 3rd, 5th, 7th and 10th days after spray (DAS) for two sprays during two seasons, only the pooled mean data was used. Pooled mean after the first and second spray of the two seasons (2017-18 and 2019-20), showed that the incidence of T. tabaci and A. biguttula biguttula reduced considerably and registered 8.25 and 3.01 per three leaves, respectively in the plots sprayed with combi-product, lessenta 80 WG (fipronil 40%+ imidacloprid 40%WG) @ 125 g ai/ ha followed by fipronil 40%+ imidacloprid 40%WG (a) 100 g ai/ ha (8.68 and 3.42/ 3 leaves) and fipronil 40%+ imidacloprid 40%WG @ 75g ai/ ha (9.55 and 3.98/3 leaves). Among the other treatments, fipronil 5 %SC @ 125 g ai/ ha (11.42 and 6.47/ 3 leaves) recorded minimum T. tabaci and A. biguttula biguttula incidence, respectively. Per cent reduction of T. tabaci and A. biguttula biguttula incidence was higher in the combiproduct treatment, fipronil 40%+ imidacloprid 40%WG (a) 125 g a.i/ ha (74.56% and 70.94%, respectively) followed by fipronil 40%+ imidacloprid 40%WG (a) 100 g ai/ ha (73.23% and 66.99%, respectively) and fipronil 40%+ imidacloprid 40%WG @ 75g ai/ ha (70.55% and 61.60%, respectively), whereas, Monocrotophos 36%SL @ 437 g ai/ ha recorded lowest % reduction of T. tabaci (60.01%) and imidacloprid 17.8%SL recorded lowest % reduction of A. biguttula biguttula (33.11%).

The observations in treatments like fipronil 40%+ imidacloprid 40%WG, fipronil 5%SC, imidacloprid 17.8 SL, lambda cyhalothrin 5%EC and Monocrotophos 36%SL were revealed that there was non-significant difference among the treatments (Table 1), and found to be safer towards natural enemies viz., coccinellids and chrysopids (Table 1). A combi product, fipronil 40 +imidacloprid 40%WG proved to be better choice in effective management of both A. biguttula biguttula and T. tabaci incidence while safer to the natural enemies as they may not have come in direct contact with the insecticide due its systemic action and the toxicant might have lost its lethal effect after its activity in the host. The pooled data (2017-18 and 2019-20) on seed cotton yield obtained from the different treatments of test chemicals was significantly higher compared to untreated control (10.42 q/ ha) (Table 1). The higher

Table 1. Efficacy of fipronil 40%+ imidacloprid 40%WG against T. tabaci and A. biguttula biguttula in

Efficacy of combi-product fipronil 40%+ imidacloprid 40%wg against leafhopper and thrips in cotton Shiddalingappa V Hugar et al. dose of fipronil 40%+ imidacloprid 40%WG @ 125 g/ ha registered 13.99 q/ ha was statistically comparable with fipronil 40%+ imidacloprid 40%WG @ 100 g/ha (13.58 q/ ha) and fipronil 40%+ imidacloprid 40%WG @ 75 g/ ha (12.86 q/ ha). Fipronil 5 SC @ 125 g/ ha (11.62 q/ha) and imidacloprid 17.8 SL @ 250 ml/ ha (11.48 q/ ha) were next best options (Table 1).

The present findings are inline with the work of Patil et al. (2009) who recorded that fipronil 5%SC @ 800 g/ ha registered least number of T. tabaci and A. biguttula *biguttula* (8.47 and 3.45/3 leaves, respectively) and significantly highest seed cotton yield of 27.23 q/ ha (2007) and 27.50 q/ha (2008) was harvested. Similarly, Sathyan et al. (2016) reported that the fipronil 5 SC was the most effective insecticide (3.15/3 leaves) with 83.06% reduction in T. Tabaci incidence compared to the mean of untreated check (18.60/ 3 leaves) and Rohini (2010) reported that fipronil 5 SC at 0.01% effective against T. tabaci incidence. Fipronil 5%SC recorded least number of T. tabaci 3.51 per three leaves in cotton (Zanwar et al., 2012). Singh et al. (2002) and Sinha et al. (2007) reported that fipronil @ 50 g ai/ha at fortnightly interval was found to be the best treatment against the A. biguttula biguttula. Among the different tested insecticides, fipronil 5%SC @ 50 g.a.i/ ha has shown 76.7% reduction of T. tabaci, followed by fipronil 80%WG@ 50 g.a.i/ ha, acephate 75%SP @ 750 g.a.i/ ha and imidacloprid 70%WG @ 21g.a.i/ ha has shown 74.5, 71.6 and 69.0% reduction over the control after ten days after treatment. Furthermore, it has recorded highest yield of 13.5 q/ ha when compared to other treatments (Ramalakshmi et al., 2020)

The reports on the bioefficacy of the nicotinoid molecules viz., imidacloprid in spray and seed dressing formulation against sucking pests of cotton and other crops has been well proved (Vastrad, 2003: Patil and Rajanikanth, 2004). Saleem et al. (2001) reported that imidacloprid 17.8 SL effectively controlled sucking pests up to seven days after the spray in cotton. Baraskar and Paradkar (2020) concluded that two sprays of flonicamid 50 WP @ 150 g/ ha, thiamethoxam 25%WG @ 200 g/ ha, difenthiuron 50 WP @ 600 g/ ha and fipronil 5%SC @1000 ml/ ha were found very effective in controlling major sucking pests of Btcotton. Asif et al. (2016) reported that imidacloprid and lambda cyhalothrin were the effective chemicals in the management of cotton sucking pests. There was 20.9% reduction of thrips incidence observed in diafenthiuron, acetamiprid and fipronil sequential spray (Ram Prasad and Ashwini, 2021). The binding

sites of imidacloprid (belonging to the neonicotinoids group) to nicotinic acetylcholine receptors (nAChRs) and fipronil (belonging to the phenyl-pyrazole group) to γ -aminobutyric acid (GABA) receptors in the nervous systems of vertebrates are different from those in insects. In general, vertebrates have lower numbers of nicotinic receptors with high affinity to neonicotinoids, which is why neonicotinoids generally show a higher toxicity to invertebrates (Borota et al., 2021) than vertebrates (Tomizawa and Casida, 2003). Similarly, the binding of fipronil to insect GABA receptors is tighter than that observed for vertebrate receptors (Cole et al. 1993; Gant et al. 1998; Hainzl et al., 1996; Ratra and Casida 2001; Ratra et al., 2001; Narahashi et al., 2010). Thus, combination of imidacloprid and fipronil make them comparatively safe for agricultural workers. Further the neonicotinoids and fipronil are also relatively persistent, offering the potential for long-term crop protection activity. However, it is the systemic nature of these insecticides that has made them so successful (Simon-Delso et al., 2015).

ACKNOWLEDGEMENTS

Authors thank the Directorate of Research, University of Agricultural Sciences, Dharwad, Karnataka, India for permitting us to conduct this experiment.

AUTHOR CONTRIBUTION STATEMENT

S V Hugar conducted the experiments and analysed the data. S S Udikeri prepared the manuscript. All the authors read and approved the manuscript.

CONFLICT OF INTEREST

No conflict of interest
